Figures 5A-5B depict a high level flow chart which illustrates tracking the number of insertions of integrated circuit devices in accordance with the present invention. The process starts as depicted by block 500 and thereafter passes to block 502 which illustrates the computer system being in standby mode whereby the computer system continuously receives standby power. Next, block 504 depicts a determination of whether or not a user has invoked a menu to use to manually update the insertion information. A technician might have inserted an IC device, such as an MCM assembly, while the data processing system was completely powered off. In this case, because there was a loss of standby power, the data processing system could not detect the insertion. This insertion must be entered manually. If a determination is made that a user has invoked a menu to use to manually update the insertion information, the process passes to block 506 which illustrates receiving a manual update to one or more insertion count fields. The process then passes to block 508. Referring again to block 504, if a determination is made that a user has not invoked a menu to use to manually update the insertion information, the process passes to block 508.

The configuration data 600 is stored in NVRAM and is used by the service processor as describe above in Figures 5A-5B, blocks 518 and 520, to determine if a new MCM assembly has been inserted. Configuration data 600 may also be used by the service processor for other purposes.
